### 3.26.6.2 SD Host Controller Configuration Registers (SDHC)

The registers are accessed directly mapped by [D14F7x10 \[Base Address Reg 0\]](#) and [D14F7x14 \[Upper Base Address Reg 0\]](#). For full details refer to the *SD Specification Part A2 SD Host Controller Standard Specification Version 3.00*.

#### SDHCx00 SDHC System Address / Argument 2

| Bits  | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
|-------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31:16 | <b>SysAddr1.</b> Read-write. Reset: 0. System Address upper bits. Updating this register clears DMA_WAIT. It indicates system memory address for DMA. When DMA transfer detects the DMA Buffer Boundary specified by the Host DMA Buffer Boundary in the Block Size register, SD controller asserts DMA_WAIT. Also SD controller generates DMA interrupt at this time when corresponding bits in the Normal Interrupt Status Enable register and Normal Interrupt Signal Enable register are set. While ADMA is enabled, this register will not be used. |
| 15:0  | <b>SysAddr0.</b> Read-write. Reset: 0. System Address lower bits. Updating this register clears DMA_WAIT.                                                                                                                                                                                                                                                                                                                                                                                                                                                |

#### SDHCx04 SDHC Block CS

Block Size and Block Count.

| Bits  | Description                                                                                                                                                                                                                                                                                                                       |
|-------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31:16 | <b>BlkCnt.</b> Read-write. Reset: 0. Block Count. It indicates block count of multiple data transfer. It is enabled when the Block Count Enable bit (D01) in the Transfer Mode register is set to 1. It is decremented after each block data transmission. During infinite data transmission, setting of this bit is meaningless. |
| 15    | Reserved.                                                                                                                                                                                                                                                                                                                         |

|       |                                                                                                                                                                                                                |                   |             |                   |
|-------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------------|-------------|-------------------|
| 14:12 | <b>DmaBufBndry.</b> Read-write. Reset: 0. Host DMA Buffer Boundary. Indicates the contiguous buffer size in the system memory. When the boundary is reached, DMA interrupt will be generated.                  |                   |             |                   |

Reset: 0. 1=Re-tuning should be performed.                                                                                                                                                                                                                                                                                                                               |
| 11:9  | Reserved.                                                                                                                                                                                                                                                                                                                                                                                                 |
| 8     | <b>Sdio.</b> Read; Write-1-to-clear. Reset: 0. SDIO Card Interrupt. Writing 1 to this register does not clear this bit. To clear this bit, interrupt factor of SDIO cards should be cleared. The value of this bit is latched internally as long as the Card Interrupt bit (D08) in the Normal Interrupt Status Enable register is 1.                                                                     |
| 7     | <b>CardRem.</b> Read; Write-1-to-clear. Reset: 0. Card Removal.                                                                                                                                                                                                                                                                                                                                           |
| 6     | <b>CardIns.</b> Read; Write-1-to-clear. Reset: 0. Card Insertion.                                                                                                                                                                                                                                                                                                                                         |
| 5     | <b>BufRdRdy.</b> Read; Write-1-to-clear. Reset: 0. Buffer Read Ready. In the case where Auto CMD12 is enabled and last block has been transferred, Auto CMD12 will be issued prior to this bit being set to 1. Clearing this bit should be done before buffer reading, because SD controller has dual buffer and the next Buffer Read Ready interrupt may occur immediately.                              |
| 4     | <b>BufWrRdy.</b> Read; Write-1-to-clear. Reset: 0. Buffer Write Ready. Clearing this bit should be done before buffer writing, because the SD controller has dual buffer and the next Buffer Write Ready interrupt may occur immediately.                                                                                                                                                                 |
| 3     | <b>DmaEvt.</b> Read; Write-1-to-clear. Reset: 0. DMA Interrupt. It is set when internal counter reaches the value designated by Host DMA Buffer Boundary. It should be cleared by Host Driver after System Address Register is updated.                                                                                                                                                                   |
| 2     | <b>BlockGapEvt.</b> Read; Write-1-to-clear. Reset: 0. Block Gap Event. It indicates the timing of next block gap, which was requested by the Stop At Block Gap Request. In case of write transaction, this interrupt will be generated before busy completion.                                                                                                                                            |
| 1     | <b>DatDone.</b> Read; Write-1-to-clear. Reset: 0. Data Transfer Complete. Indicates the timing for completion of data transaction, which includes the completion at the block gap by the Stop At Block Gap Request. When some errors are detected during data transaction, this bit will not be set. In the case where Auto CMD12 is enabled, Auto CMD12 will be issued prior to this bit being set to 1. |
| 0     | <b>CmdDone: cmdDone (r).</b> Read-write. Reset: 0. Command Complete. The end bit of the command response is received. In the case of commands with no response, the end of the command.                                                                                                                                                                                                                   |

## SDHCx34 SDHC\_INT\_MASK

| 20    | <b>MsiMappingCapability: MSI Mapping Capability.</b> Value: 1. 1=This device supports MSI mapping.                                                                                                                                                                  |
| 19:10 | Reserved.                                                                                                                                                                                                                                                           |
| 9     | <b>FastBack2BackEnable: Fast Back-to-Back Enable.</b> Value: 0. ACPI/SMBus does not support fast back-to-back.                                                                                                                                                      |
| 8     | <b>SERREnable: System Error Enable.</b> Read-write. Reset: 0. 1=Enable system error reporting.                                                                                                                                                                      |
| 7     | <b>WaitCycleControl: Wait Cycle Control.</b> Value: 0. 0=This module does not use address stepping.                                                                                                                                                                 |

|   |                                                                                                                                                                                                                                                                                                        |
|---|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 6 | <b>ParityErrorResponse: Parity Error Response.</b> Read-write. Reset: 0. This bit controls the device's response to parity errors. 1=The device must take its normal action when a parity error is detected. 0=The device must ignore any parity errors that it detects and continue normal operation. |
| 5 | <b>VGAPaletteSnoop: VGA Palette Snoop.</b> Value: 0. This bit does not apply to this module.                                                                                                                                                                                                           |
| 4 | <b>MemoryWriteInvalidateEnable: Memory Write and Invalidate Enable.</b> Value: 0. This module does not generate Memory Write and Invalidate command.                                                                                                                                                   |
| 3 | <b>SpecialCycle: Special Cycle.</b> Value: 0. This module does not respond to special cycle.                                                                                                                                                                                                           |
| 2 | <b>BusMaster: Bus Master.</b> Value: 0. ACPI/SMBus does not have PCI master.                                                                                                                                                                                                                           |
| 1 | <b>MemorySpace: Memory Space.</b> Read-write. Reset: 1. 1=Enable the device to respond to memory space accesses.                                                                                                                                                                                       |
| 0 | <b>IOSpace: IO Space.</b> Read-write. Reset: 1. 1=Enable the device to respond to IO space accesses.                                                                                                                                                                                                   |

#### D14F0x08 Revision ID/Class Code

| Bits | Description                                                                                                                                                 |
|------|-------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31:8 | <b>ClassCode: Class Code.</b> Value: C0500h. Specifies a SMBUS controller.                                                                                  |
| 7:0  | <b>RevisionID: Revision ID.</b> Value: IF (RevA0) THEN 39h. ELSEIF (RevA1) THEN 3Ah. ENDIF. BOZO RevA1 should be an xref to the soc XX_A1 definition (Kurt) |

#### D14F0x0C Cache Line Size

| Bits  | Description                                                                                                                                                                                                                      |
|-------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31:24 | <b>Bist.</b> Value: 0. The module has no built-in self-test and so this is always 0.                                                                                                                                             |
| 23:16 | <b>HeaderType: Header Type.</b> Value: 80h. This device is a multifunction device.                                                                                                                                               |
| 15:8  | <b>LatencyTimer: Latency Timer.</b> Value: 0. This register specifies the value of the Latency Timer. This is not used in this module and so it is always 0.                                                                     |
| 7:0   | <b>CacheLineSize: Cache Line Size.</b> Value: 0. This register specifies the system cache line size. This module does not use Memory Write and Invalidate command and so this register is not applicable. It is hard coded to 0. |

#### D14F0x10 Base Address 0

| Bits | Description                                                                     |
|------|---------------------------------------------------------------------------------|
| 31:0 | <b>BaseAddress0: Base Address 0.</b> Value: 0. Not used and is hard coded to 0. |

#### D14F0x14 Base Address 1

| Bits | Description                                                                     |
|------|---------------------------------------------------------------------------------|
| 31:0 | <b>BaseAddress1: Base Address 1.</b> Value: 0. Not used and is hard coded to 0. |

**D14F0x18 Base Address 2**

| Bits | Description                                                                     |
|------|---------------------------------------------------------------------------------|
| 31:0 | <b>BaseAddress2: Base Address 2.</b> Value: 0. Not used and is hard coded to 0. |

**D14F0x1C Base Address 3**

| Bits | Description                                                                     |
|------|---------------------------------------------------------------------------------|
| 31:0 | <b>BaseAddress3: Base Address 3.</b> Value: 0. Not used and is hard coded to 0. |

**D14F0x20 Base Address 4**

| Bits | Description                                                                     |
|------|---------------------------------------------------------------------------------|
| 31:0 | <b>BaseAddress4: Base Address 4.</b> Value: 0. Not used and is hard coded to 0. |

**D14F0x24 Base Address 5**

| Bits | Description                                                                     |
|------|---------------------------------------------------------------------------------|
| 31:0 | <b>BaseAddress5: Base Address 5.</b> Value: 0. Not used and is hard coded to 0. |

**D14F0x28 Cardbus CIS Pointer**

| Bits | Description                                                                               |
|------|-------------------------------------------------------------------------------------------|
| 31:0 | <b>CardbusCISPointer: Cardbus CIS Pointer.</b> Value: 0. Not used and is hard coded to 0. |

**D14F0x2C Subsystem Vendor ID**

| Bits  | Description                                                              |
|-------|--------------------------------------------------------------------------|
| 31:16 | <b>SubsystemID: Subsystem ID.</b> Write-once. Reset: 780Bh.              |
| 15:0  | <b>SubsystemVendorID: Subsystem Vendor ID.</b> Write-once. Reset: 1022h. |

**D14F0x30 Expansion ROM Base Address**

| Bits | Description                                                                     |
|------|---------------------------------------------------------------------------------|
| 31:8 | Reserved.                                                                       |
| 7:0  | <b>ExpansionROMBaseAddress: Expansion ROM Base Address.</b> Value: 0. Not used. |

**D14F0x34 Capability Pointer**

| Bits | Description                                                        |
|------|--------------------------------------------------------------------|
| 31:8 | Reserved.                                                          |
| 7:0  | <b>CapabilityPointer: Capability Pointer.</b> Read-only. Reset: 0. |

**D14F0x3C Interrupt Line**

| Bits  | Description                                                                               |
|-------|-------------------------------------------------------------------------------------------|
| 31:24 | <b>MaxLat.</b> Value: 0. Device has no requirements for the setting.                      |
| 23:16 | <b>MinGnt.</b> Value: 0. Device has no requirements for the setting.                      |
| 15:8  | <b>InterruptPin: Interrupt Pin.</b> Value: 0. 0=This module does not generate interrupts. |
| 7:0   | <b>InterruptLine: Interrupt Line.</b> Value: 0. This module does not generate interrupts. |

**3.26.7.2 ASF (Alert Standard Format) Registers**

ASF register space is accessed through two methods:

- IO access through ASF IO base address defined by [PMx28 \[AsfEn\]](#):
  - A. Program the base address of ASF IO space through [PMx28\[AsfIoBase\]](#).
  - B. Enable ASF function and IO decoding through [PMx28\[AsfEn\]](#).
- Direct memory mapped or IO mapped access through the AcpiMmio region. The ASF registers range from [PMx24\[AcpiMmioAddr\]+900h](#) to [PMx24\[AcpiMmioAddr\]+9FFh](#). See [PMx24 \[AcpiMmioEn\]](#).

**ASFx00 HostStatus**

| Bits | Description                                                                                                                                           |
|------|-------------------------------------------------------------------------------------------------------------------------------------------------------|
| 7    | <b>LastByte.</b> Read; set-by-hardware; write-1-to-clear. Reset: 0. 0=Last byte has not received. 1=Last byte has received.                           |
| 6:5  | Reserved.                                                                                                                                             |
| 4    | <b>PECErrror.</b> Read; set-by-hardware; write-1-to-clear. Reset: 0. 0=No CRC error. 1=CRC error happened.                                            |
| 3    | <b>BusCollision.</b> Read; set-by-hardware; write-1-to-clear. Reset: 0. 0=No bus collision. 1=Bus collision.                                          |
| 2    | <b>DevError.</b> Read; set-by-hardware; write-1-to-clear. Reset: 0. 0=Slave device behaves correctly. 1=No ACK or slave device responses incorrectly. |
| 1    | <b>Intr.</b> Read; set-by-hardware; write-1-to-clear. Reset: 0. 1=Termination of a command. Whenever [HostBusy] is cleared, this bit is set.          |
| 0    | <b>HostBusy.</b> Read-only; updated-by-hardware. Reset: 0. This bit reports the status of the ASF host. 0=SM bus host is idle. 1=SM bus host is busy. |

**ASFx02 HostControl**

| Bits | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                           |      |            |      |       |      |      |      |           |      |           |      |              |      |       |      |                                     |      |          |

Write 1 to clear [HostSemaphore] bit.                                                                                                                                                                                                                                                                                                                                                                                                |
| 0 | <b>HostSemaphore.</b> Read; write-1-only. Reset: 0. Bits [0] and [2] are meant to be used as software semaphore between the host and IMC. When both host and IMC want to use the same resource, they can write to these semaphore bits first, followed by a read. If the read returns a 1 in the semaphore bit, it means it has established the semaphore first. Write 1 to set this bit. This bit can only be set when EcSemaphore is clear. Writing 0 has no effect. Read returns the value of this bit. |

### ASFx15 SlaveEn

### ASFx16 DelayMasterTimer

| Bits | Description                                                                                                                                         |
|------|-----------------------------------------------------------------------------------------------------------------------------------------------------|
| 7:0  | <b>FairArbTimer.</b> Read-write. Reset: 10h. Specify how long ASF master has to wait before submitting next packet. Wait time = FairArbTimer* 2 us. |

### 3.26.7.3 SMBus Registers

SMBus register space is accessed through two methods:

- IO access through SMBus IO base address defined by [PMx2C \[Smbus0En\]](#):
  - Program the base address of SMBus IO space through [PMx2C\[SmBus0IoBase\]](#).
  - Enable SMBus function and IO decoding through [PMx2C\[SmBus0En\]](#).
- Direct memory mapped or IO mapped access through the AcpiMmio region. The SMBus registers range from [PMx24\[AcpiMmioAddr\]+A00h](#) to [PMx24\[AcpiMmioAddr\]+AFFh](#). See [PMx24 \[AcpiMmioEn\]](#).

### SMBUSx00 SMBusStatus

| Bits | Description                                                                                                                                                                             |
|------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 7:5  | Reserved.                                                                                                                                                                               |
| 4    | <b>Failed.</b> Write-1-to-clear; set-by-hardware; read. Reset: 0. 1=A Failed bus transaction. IF ( <a href="#">SMBUSx02[Kill]</a> ==1) THEN <a href="#">SMBUSx00[Failed]</a> =1. ENDIF. |
| 3    | <b>BusCollision.</b> Write-1-to-clear; set-by-hardware; read. Reset: 0. 1=An SMBus transaction collision.                                                                               |

|   |                                                                                                                                                                                                                                                 |
|---|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 2 | <b>DeviceErr.</b> Write-1-to-clear; set-by-hardware; read. Reset: 0. 1=An error of one of the following: <ul style="list-style-type: none"> <li>• Illegal command field.</li> <li>• Unclaimed cycle</li> <li>• Host device time-out.</li> </ul> |
| 1 | <b>SMBusInterrupt.</b> Write-1-to-clear; set-by-hardware; read. Reset: 0. 1=The completion of the last host command.                                                                                                                            |
| 0 | <b>HostBusy.</b> Read-only. Reset: 0. 1=The SMBus controller is in the process of completing a command. When this bit is set, software should not access any other SMBus registers.                                                             |

### SMBUSx01 SMBusSlaveStatus

| Bits | Description                                                                                                                                                                                                          |
|------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 7:6  | Reserved.                                                                                                                                                                                                            |
| 5    | <b>AlertStatus.</b> Read-only. Reset: 0. This bit is set by hardware to indicate an SMBALERT_ signal. This function is not supported.                                                                                |
| 4    | <b>Shadow2Status.</b> Write-1-to-clear; set-by-hardware; read. Reset: 0. This bit is set by hardware to indicate a slave cycle address match of the SMB_Shadow2 port.                                                |
| 3    | <b>Shadow1Status.</b> Write-1-to-clear; set-by-hardware; read. Reset: 0. This bit is set by hardware to indicate a slave cycle address match of the SMB_Shadow1 port.                                                |
| 2    | <b>SlaveStatus.</b> Write-1-to-clear; set-by-hardware; read. Reset: 0. This bit is set by hardware to indicate a slave cycle event match of the SMBus slave command and SMBus Slave Event match.                     |
| 1    | <b>SlaveInit.</b> RAZ; write-1-only. Reset: 0. Writing a 1 to this bit initializes the slave.                                                                                                                        |
| 0    | <b>SlaveBusy.</b> Read-only. Reset: 0. This bit indicates the SMBus controller slave interface is in the process of receiving data. Software should not try to access any other SMBus register when this bit is set. |

### SMBUSx02 SMBusControl

| Bits      | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                               |      |            |      |                     |      |                    |      |                         |      |                         |      |          |      |                     |           |          |

|---|------------------------------------------------------------------------------------------------------------------------------------|
| 1 | <b>Kill.</b> Read-write. Reset: 0. Stop the current host transaction in process.                                                   |
| 0 | <b>InterruptEnable.</b> Read-write. Reset: 0. 1=Enable the generation of interrupts on the completion of current host transaction. |

### SMBUSx03 SMBusHostCmd

| Bits | Description                                                                                                                         |
|------|-------------------------------------------------------------------------------------------------------------------------------------|
| 7:0  | <b>SMBusHostCmd.</b> Read-write. Reset: 0. This field contains the data transmitted in the command field of SMBus host transaction. |

### SMBUSx04 SMBusAddress

| Bits | Description                                                                                               |
|------|-----------------------------------------------------------------------------------------------------------|
| 7:1  | <b>SMBusAddr.</b> Read-write. Reset: 0. This field contains the 7-bit address of the target slave device. |
| 0    | <b>SMBusRdWr.</b> Read-write. Reset: 0. 0=Execute a Write command. 1=Execute a Read command.              |

### SMBUSx05 SMBusData0

| Bits | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
|------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 7:0  | <b>SMBusData0.</b> Read-write. Reset: 0. This register should be programmed with a value to be transmitted in the data 0 field of an SMBus host interface transaction. For Block Write commands, the count of the memory should be stored in this field. The value of this register is loaded into the block transfer count field. A valid value for block command count is between 1 and 32. For block reads, count received from SMBus device is stored here. |

### SMBUSx06 SMBusData1

| Bits | Description                                                                                                                                                                                                                                                                                                                                                                                                                                             |
|------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 7:0  | <b>SMBusData1.</b> Read-write. Reset: 0. This register should be programmed with a value to be transmitted in the data 1 field of an SMBus host interface transaction. When $(\text{SMBUSx14}[\text{SMBusPoll2Byte}] == 1) \ \& \ ((\text{SMBUSx02}[\text{SMBusProtocol}] == \text{Byte Read/Write}) \mid (\text{SMBUSx02}[\text{SMBusProtocol}] == \text{Byte Data Read/Write}))$ , this register is used as the data field in the second transaction. |

### SMBUSx07 SMBusBlockData

| Bits | Description                                                                                                                      |
|------|----------------------------------------------------------------------------------------------------------------------------------|
| 7:0  | <b>SMBusBlockData.</b> Read-write. Reset: 0. This register is used to transfer data into or out of the block data storage array. |

**SMBUSx08 SMBusSlaveControl**

| Bits | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
|------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 7    | <b>ClrEcSemaphore.</b> Read-write; Cleared-by-hardware. Reset: 0. Write 1 to clear EcSemaphore bit. Writing 0 has no effect.                                                                                                                                                                                                                                                                                                                                                                                      |
| 6    | <b>EcSemaphore.</b> Read-write. Reset: 0. Write 1 to set this bit. This bit can only be set when HostSemaphore is clear. Writing 0 has no effect. Reading returns the value of this bit                                                                                                                                                                                                                                                                                                                           |
| 5    | <b>ClrHostSemaphore.</b> Read-write; Cleared-by-hardware. Reset: 0. Write 1 to clear HostSemaphore bit. Writing 0 has no effect.                                                                                                                                                                                                                                                                                                                                                                                  |
| 4    | <b>HostSemaphore.</b> Read-write. Reset: 0. Bits 4 and 6 are meant to be used as software semaphore between the host and embedded controller. When both host and IMC want to use the same resource, they can write to these semaphore bits first, followed by a read. If the read returns a 1 in the semaphore bit, it means it has established the semaphore first. Write 1 to set this bit. This bit can only be set when EcSemaphore is clear. Writing 0 has no effect. Reading returns the value of this bit. |
| 3    | <b>SMBusAlertEnable.</b> Read-only. Reset: 0. Enable the generation of an interrupt or resume event on the assertion of AMBALERT_ signal. (This function is not supported).                                                                                                                                                                                                                                                                                                                                       |
| 2    | <b>SMBusShadow2En.</b> Read-write. Reset: 0. Enable the generation of an interrupt or resume event upon an external SMBus master generating a transaction with an address that matches the SMBus Shadow 2 register.                                                                                                                                                                                                                                                                                               |
| 1    | <b>SMBusShadow1En.</b> Read-write. Reset: 0. Enable the generation of an interrupt or resume event upon an external SMBus master generating a transaction with an address that matches the SMBus Shadow 1 register.                                                                                                                                                                                                                                                                                               |
| 0    | <b>SlaveEnable.</b> Read-write. Reset: 0. Enable the generation of an interrupt or resume event upon an external SMBus master generating a transaction with an address that matches the host controller slave port of 10h, a command field that matches the SMBus slave control register, and a match of corresponding enabled events.                                                                                                                                                                            |

**SMBUSx09 SMBusShadowCmd**

| Bits | Description                                                                                                                                                                                                                            |
|------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 7:0  | <b>SMBusShadowCmd.</b> Read-write. Reset: 0. This field contains the command value that was received during an external SMBus master access whose address field matched the host slave address (10h) or one of the slave shadow ports. |

**SMBUSx0A SMBusSlaveEvent**

| Bits | Description                                                                                                                                                                                                                                                                                                                                                                                                          |
|------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 15:0 | <b>SMBusSlaveEvent.</b> Read-write. Reset: 0. This field contains data bits used to compare against incoming data to the SMBus Slave Data register. When a bit in this register is 1 and a corresponding bit in SMBus Slave register is set, then an interrupt or resume event is generated if the command value matches the value in the SMBus slave control register and the access was to SMBus host address 10h. |

**SMBUSx0C SlaveData**

| Bits | Description                                                                                                                                                                                                                                                         |
|------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 15:0 | <b>SlaveData</b> . Read-write. Reset: 0. This field contains the data value which was transmitted during an external SMBus master access whose address field matched one of the slave shadow port addresses or the SMBus host controller slave port address of 10h. |

**SMBUSx0E SMBusTiming**

| Bits | Description                                                                                                                                                                      |
|------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 7:0  | <b>SMBusTiming</b> . Read-write. Reset: B0h. This register controls the frequency on the SMBUS. The formula to calculate the frequency is: Frequency = 66 MHz/(SMBusTiming * 4). |

**SMBUSx10 I2CbusConfig**

| Bits | Description                                                            |
|------|------------------------------------------------------------------------|
| 7:4  | <b>I2CRevision</b> . Read-write. Reset: 0. Sm bus controller revision. |
| 3:1  | Reserved.                                                              |
| 0    | <b>I2CbusInterrupt</b> . Read-write. Reset: 0. 0=SMI#. 1=IRQ.          |

**SMBUSx11 I2CCommand**

| Bits | Description                                                                                                                                                                               |
|------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 7:0  | <b>I2Ccommand</b> . Read-write. Reset: 0. I2C Host Slave Command. This value specifies the command value to be matched for I2C master accesses to the I2Ccontroller host slave interface. |

**SMBUSx12 I2CShadow1**

| Bits | Description                                                                                                                                                                                 |
|------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 7:1  | <b>I2CslaveAddr1</b> . Read-write. Reset: 0. SMBus Slave Address for shadow port 1. This value specifies the address used to match against incoming I2C addresses for Shadow port 1.        |
| 0    | <b>ReadWriteShadowPort1</b> . Read-write. Reset: 0. This bit must be programmed to 0 because I2C slave controller only responds to Word Write Transaction. 0=Write command. 1=Read command. |

**SMBUSx13 I2Cshadow2**

| Bits | Description                                                                                                                                                                                 |
|------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 7:1  | <b>I2CslaveAddr2</b> . Read-write. Reset: 0. SMBus Slave Address for shadow port 2. This value specifies the address used to match against incoming I2C addresses for Shadow port 2.        |
| 0    | <b>ReadWriteShadowPort2</b> . Read-write. Reset: 0. This bit must be programmed to 0 because I2C slave controller only responds to Word Write Transaction. 0=Write command. 1=Read command. |

**SMBUSx14 SMBusAutoPoll**

| Bits      | Description                                                                                                                                                                                                                                                                                                                                                                                                               |      |            |      |                        |      |                       |      |                       |      |                       |           |                     |
|-----------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------|------------|------|------------------------|------|-----------------------|------|-----------------------|------|-----------------------|-----------|---------------------|
| 7         | <b>SMBusPoll2Byte.</b> Read-write. Reset: 1. When set, if ((SMBUSx02[SMBusProtocol]==Byte Read/Write)   (SMBUSx02[SMBusProtocol]==Byte Data Read/Write), the last command will be performed twice at each polling interval. SMBUSx06 [SMBusData1] contains data transmitted and retrieved from the second transaction. SMBUSx17 [SMBusHostCmd2] contains data transmitted in the command field in the second transaction. |      |            |      |                        |      |                       |      |                       |      |                       |           |                     |
| 6:4       | Reserved.                                                                                                                                                                                                                                                                                                                                                                                                                 |      |            |      |                        |      |                       |      |                       |      |                       |           |                     |

| 011b      | poll every 1/2 second                                                                                                                                                                                                                                                                                                                                                                                                     |      |            |      |                        |      |                       |      |                       |      |                       |           |                     |
| 111b-100b | poll every 1 second                                                                                                                                                                                                                                                                                                                                                                                                       |      |            |      |                        |      |                       |      |                       |      |                       |           |                     |
| 0         | <b>SMBusAutoPollEn.</b> Read-write. Reset: 0. 1=SMBUS will periodically execute the last command whenever SMBUSx15 [SMBusCounter] expires. The polling interval is defined by [SMBusPollPeriod]. The purpose of this function is to use the SMBUS to read CPU temperature via TSI. Values in SMBUSx05 [SMBusData0] and SMBUSx06 [SMBusData1] are to be used for controlling the fan speed.                                |      |            |      |                        |      |                       |      |                       |      |                       |           |                     |

**SMBUSx15 SMBusCounter**

| Bits | Description                                                                                                                                                                                                                                                                                                  |
|------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 7:0  | <b>SMBusCounter.</b> Read-only. This counter specifies the remaining time until the next read. The interval is based on SMBUSx14[SMBusPollPeriod]. For example, if SMBUSx14[SMBusPollPeriod] is 000b, then each tick in this counter represents $1/16 / 256 = 244\mu\text{s}$ . BOZO: Reset missing in spec. |

**SMBUSx16 SMBusStop**

| Bits | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
|------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 15:1 | Reserved.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| 0    | <b>SMBusPausePoll.</b> Read-write. Reset: 0. This is to be used as a semaphore mechanism by software to stop the next polling. If software wants to use the SMBUS for other purpose but the hardware has already been enabled (SMBUSx14[SMBusAutoPollEn]=1) to perform auto polling, software can halt the next polling by setting this bit to 1. If the halt is successful, this bit will return 1. If the HW has already started the polling operation at the same time software tries to set this bit, this bit will return 0. When the pending polling operation is finally complete, this bit will then get set. When this bit is set, polling counter will temporarily stop (not reset). It is now safe for software to access the SMBUS. Upon completion, software must restore the previous command in the appropriate register prior to setting this bit. software should also clear this bit so the counter can resume counting. |

**SMBUSx17 SMBusHostCmd2**

---

| Bits | Description                                                                                                                                                                                                                                                   |

| 7:0  | <b>SMBusHostCmd2</b> . Read-write. Reset: 0. This field contains the data transmitted in the command field in the second command when ( <a href="#">SMBUSx14</a> [SMBusPoll2Byte]==1) and ( <a href="#">SMBUSx02</a> [SMBus-Protocol]==Byte Data Read/Write). |

### 3.26.8 IOAPIC Registers

IOAPIC configuration registers are accessed through IOAPIC base address defined by [PMx34 \[IoApicEn\]](#):

1. Select the IOAPIC register space to be memory mapped or IO mapped through [PMx34\[IoApicMmio\]](#).
2. Program the IOAPIC base address through [PMx34\[IoApicBaseAddr\]](#).
3. Enable IOAPIC decoding through [PMx34\[IoApicEnable\]](#).

#### IOAPICx00 IO Register Select Register

| Bits | Description                                                                                                                                                                                                  |
|------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31:8 | Reserved.                                                                                                                                                                                                    |
| 7:0  | <b>IndirectAddressOffset</b> . Read-write. Reset: 0. Indirect Address Offset to IO Window Register. It is used to determine which register is manipulated during an IO Window Register read/write operation. |

#### IOAPICx10 IO Window Register

| Bits | Description                                                                                                             |
|------|-------------------------------------------------------------------------------------------------------------------------|
| 31:0 | <b>IOWindow</b> . Read-write. Reset: 0. Mapped by <a href="#">IOAPICx00</a> to the designated indirect access register. |

#### IOAPICx10\_x00 IOAPIC ID Register

This register is not used in IOxAPIC PCI bus delivery mode.

| Bits  | Description                                                                                                                                                                                      |

| 7:0   | <b>Vector.</b> Read-write. Reset: 0. Interrupt vector associated with this interrupt input                                                                                                                                                                                                                                                                                                                      |      |            |      |            |      |       |      |     |      |                 |      |      |      |         |      |          |      |          |      |        |

**IOAPICx20 IRQ Pin Assertion Register**

| Bits | Description                                                                                                                                                                                                                                                                                                         |
|------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31:8 | Reserved.                                                                                                                                                                                                                                                                                                           |
| 7:0  | <b>InputIrq.</b> Read-write. Reset: 0. IRQ number for the requested interrupt. A write to this register will trigger an interrupt associated with the redirection table entry referenced by the IRQ number. Currently the redirection table has 24 entries. Writes with IRQ number greater than 17h have no effect. |

**IOAPICx40 EOI Register**

| Bits | Description                                                                                                                                                                                                                                                                   |
|------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31:8 | Reserved.                                                                                                                                                                                                                                                                     |
| 7:0  | <b>Vector.</b> Write-only. Reset: 0. Interrupt vector. A write to this register will clear the remote IRR bit in the redirection table entry found matching the interrupt vector. This provides an alternate mechanism other than PCI special cycle for EOI to reach IOxAPIC. |

### 3.26.9 LPC-ISA Bridge

#### 3.26.9.1 Device 14h Function 3 (LPC Bridge) Configuration Registers

See 3.1 [Register Descriptions and Mnemonics] for a description of the register naming convention. See 2.7 [Configuration Space] for details about how to access this space.

| Bits | Description                                                                                  |
|------|----------------------------------------------------------------------------------------------|
| 31:8 | <b>ClassCode: Class Code.</b> Read-only. Reset: 60100h. Indicates an ISA bridge.             |
| 7:0  | <b>RevisionID: Revision ID.</b> Value: 11h. Indicates the revision level of the chip design. |

#### D14F3x0C Cache Line Size

| Bits  | Description                                                                                                                                                                                              |
|-------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31:24 | <b>Bist.</b> Read-only. Reset: 0. No BIST modes.                                                                                                                                                         |
| 23:16 | <b>HeaderType: Header Type.</b> Read-only. Reset: 80h. Identifies the type of the predefined header in the configuration space. The most significant bit is set to 1 to indicate a multifunction device. |
| 15:8  | <b>LatencyTimer: Latency Timer.</b> Read-only. Reset: 0. Specifies the value of the latency timer in units of PCICLKs.                                                                                   |
| 7:0   | <b>CacheLineSize: Cache Line Size.</b> Value: 0.                                                                                                                                                         |

#### D14F3x10 Base Address Reg 0

| Bits | Description                                                                                                                                                                                                                                                       |
|------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31:5 | <b>BaseAddress0[31:5]: Base Address 0.</b> RAZ; write-only. Reset: 7F60000h. This register has an internal value used as base address for APIC memory space. Writing to the register changes its internal value. The default internal base address is FEC0_0000h. |
| 4:0  | <b>BaseAddress0[4:0].</b> Value: 0.                                                                                                                                                                                                                               |

#### D14F3x2C Subsystem ID and Subsystem Vendor ID

| Bits  | Description                                                                    |
|-------|--------------------------------------------------------------------------------|
| 31:16 | <b>SubsystemID: Subsystem ID.</b> Write-once; Read. Reset: 780Eh.              |
| 15:0  | <b>SubsystemVendorID: Subsystem Vendor ID.</b> Write-once; Read. Reset: 1022h. |

#### D14F3x34 Capabilities Pointer

| Bits | Description |
|------|-------------|
|------|-------------|

|      |                                                                                                                                                                                     |
|------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31:8 | Reserved.                                                                                                                                                                           |
| 7:0  | <b>CapabilitiesPointer: Capabilities Pointer.</b> Read-only. Reset: IF (D14F3x78[MsiOn]==1) THEN 80h. ELSE 0. ENDIF. Specifies the starting address of the MSI capability register. |

### D14F3x40 PCI Control

| Bits | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
|------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31:8 | Reserved.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| 7    | <b>IntegratedEcPresent.</b> Read-write. Reset: 0. This bit can only be programmed by IMC. 1=IMC is present.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| 6    | <b>EcSemaphore.</b> Read-write. Reset: 0. This bit is writable by IMC and read by BIOS. This is used as the software semaphore mechanism between BIOS and IMC to see who can access the common resource. IMC should read bit [BiosSemaphore] first to see if BIOS has taken ownership of the resource. If [BiosSemaphore] == 0, then IMC should write a 1 to this bit and then follow by a read to see if this bit is set. If this bit is set, it means IMC has successfully taken ownership of the resource. If this bit returns a 0 and [BiosSemaphore] returns a 1, then BIOS has taken ownership first. IMC should always clear this bit after it has completed its access to the resource.     |
| 5    | <b>BiosSemaphore.</b> Read-write. Reset: 0. This bit is writable by BIOS and read by the IMC. This is used as the software semaphore mechanism between BIOS and IMC to see who can access the common resource. BIOS should read bit [EcSemaphore] first to see if IMC has taken ownership of the resource. If [EcSemaphore] == 0, then BIOS should write a 1 to this bit and then follow by a read to see if this bit is set. If this bit is set, it means BIOS has successfully taken ownership of the resource. If this bit returns 0 and [EcSemaphore] returns a 1, then IMC has taken ownership first. Software should always clear this bit after it has completed its access to the resource. |

### D14F3x4C Memory Range

| Bits  | Description                                                                                                                                                                                                   |
|-------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31:12 | <b>BaseAddress: Base Address.</b> Read-write. Reset: 0. Specifies a 4K byte memory range from {Base Address, 000h} to {Base Address, FFFh}. The range is enabled by <a href="#">D14F3x48[MemPortEnable]</a> . |
| 11:0  | Reserved.                                                                                                                                                                                                     |

### D14F3x[5C,58,54,50] ROM Protect 3, 2, 1, 0

These registers specify different ROM ranges to be protected. [SPIx1D\[SpiProtectEn0\]](#) enables the protection ranges. The addresses are within the defined ROM range if:

{RomBase, 000\_0000\_0000b} <= address[31:0] <= ({RomBase, 000\_0000\_0000b} + {0\_0000\_0000\_0000b, RomOffset, 11\_1111\_1111b}).

For host, these registers can only be written once after hardware reset; Subsequent writes to it have no effect. For IMC, these registers are always read-writable.

| Bits  | Description                                                                                                                                                                           |
|-------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31:11 | <b>RomBase: ROM Base.</b> Read; write-once. Reset: 0.                                                                                                                                 |
| 10:2  | <b>RomOffset: ROM Offset.</b> Read; write-once. Reset: 0.                                                                                                                             |
| 1     | <b>ReadProtect: Read Protect.</b> Read; write-once. Reset: 0. 1=The memory range defined by this register is read-protected and reading any location in the range returns FFFF_FFFFh. |
| 0     | <b>WriteProtect: Write Protect.</b> Read; write-once. Reset: 0. 1=The memory range defined by this register is write-protected and writing to the range has no effect.                |

### D14F3x60 PCI Memory Address for LPC Target Cycles

This register contains the upper 16 bits of the start and end address of the LPC memory target range. The lower 16 bits of the start address are considered 0s. The lower 16 bits of the end address are considered 1s. This range can be enabled or disabled using [D14F3x48\[MemoryRangePortEnable\]](#).

| Bits  | Description                                                                                                                                             |
|-------|---------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31:16 | <b>MemoryEndAddress: Memory End Address.</b> Read-write. Reset: 0. Specifies the upper 16 bits of the end address of the LPC target memory range.       |
| 15:0  | <b>MemoryStartAddress: Memory Start Address.</b> Read-write. Reset: 0. Specifies the upper 16 bits of the start address of the LPC target memory range. |

### D14F3x64 PCI IO base Address for Wide Generic Port

| Bits  | Description                                                                                                                                                                                                                                                                                                            |
|-------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31:16 | <b>IOBaseAddress1: IO Base Address 1.</b> Read-write. Reset: 0. 16-bit PCI IO base address for wide generic IO port range. This function is enabled by <a href="#">D14F3x48</a> [WideIO1Enable]. If <a href="#">D14F3x74</a> [AlternativeWideIO1RangeEnable] == 1, the range is 16 bytes; else the range is 512 bytes. |
| 15:0  | <b>IOBaseAddress0: IO Base Address 0.</b> Read-write. Reset: 0. 16-bit PCI IO base address for wide generic IO port range. This function is enabled by <a href="#">D14F3x48</a> [WideIO0Enable]. If <a href="#">D14F3x74</a> [AlternativeWideIO0RangeEnable] == 1, the range is 16 bytes; else the range is 512 bytes. |

### D14F3x68 ROM Address Range 1

This register contains the upper 16 bits of the start and end address of the ROM address range 1. The lower 16 bits of the start address are considered 0s. The lower 16 bits of the end address are considered 1s. This range can be enabled or disabled using [D14F3x48](#)[RomRange1PortEnable]. This register is used for both LPC and SPI flash.

| Bits  | Description                                                                                                                                                                                                 |
|-------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31:16 | <b>RomEndAddress1: ROM End Address 1.</b> Read-write. Reset: 0Fh. Specifies the upper 16 bits of the end address of the ROM memory address range 1. If the strap is disabled, the reset value is 0h.        |
| 15:0  | <b>RomStartAddress1: ROM Start Address 1.</b> Read-write. Reset: 08h. Specifies the upper 16 bits of the start address of the ROM memory address range 1. If the strap is disabled, the reset value is 00h. |

### D14F3x6C ROM Address Range 2

This register contains the upper 16 bits of the start and end address of the ROM address range 2. The lower 16 bits of the start address are considered 0s. The lower 16 bits of the end address are considered 1s. This range can be enabled or disabled using [D14F3x48](#)[RomRange2PortEnable]. This register is used for both LPC and SPI flash.

| Bits  | Description                                                                                                                                                                                                   |
|-------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31:16 | <b>RomEndAddress2: ROM End Address 2.</b> Read-write. Reset: FFFFh. Specifies the upper 16 bits of the end address of the ROM memory address range 2. If the strap is disabled, the reset value is 00h.       |
| 15:0  | <b>RomStartAddress2: ROM Start Address 2.</b> Read-write. Reset: FFF8h. Specifies the upper 16 bits of the start address of the ROM memory address range 2. If the strap is disabled, the reset value is 00h. |

**D14F3x74 Alternative Wide IO Range Enable**

| Bits | Description                                                                                                                                                                                                                                                                                                                                                                                                                                          |

Reset: 0. 1=Previous transfer has error. 0=Previous transfer has completed successfully.                                                                                                                                                                                                                                                           |
| 0    | <b>DmaStart.</b> Read; write-1-only; cleared-by-hardware. Reset: 0. Writing 1 to this bit causes LPC bridge to start the DMA function, with starting addresses defined by <a href="#">D14F3xB0</a> and <a href="#">D14F3xB4</a> . This bit returns the status of the DMA transfer. A return value of 0 means the DMA transfer is complete. A return value of 1 means the DMA transfer is running. |

**3.26.9.2 SPI Registers**

SPI configuration registers are accessed through SPI base address specified by [D14F3xA0 \[SPI Base\\_Addr\]](#). Software can communicate with the SPI ROM through the default memory or alternate program method:

- Memory access to the BIOS ROM address space is automatically handled by the hardware. The SPI ROM

controller translates the memory address onto the SPI bus and accesses the SPI ROM data. Any other commands besides memory read or memory write to the SPI ROM need to go through the alternate program method.

- In alternate program method, software needs to program the SpiOpCode, SpiAddress, TxByteCount, RxByteCount, put the data into the transmit FIFO, and then execute the command. The hardware communicates with the SPI ROM using these parameters. This alternate method basically allows software to issue any flash vendor specific commands such as ERASE and STATUS.

### SPIx00 SPI\_Cntrl0

Same as MacUnlockCmd0                                                                                                                                                                                                                                                                                                                                            |
| 23:16 | <b>MacUnlockCmd0.</b> IF ( <a href="#">SPIx00[SpiAccessMacRomEn]</a> ==0    <a href="#">SPIx00[SpiHostAccessRomEn]</a> ==0) THEN Read-only. ELSE Read-write. ENDIF. Reset: 4h. This field is used to compare against the opcode sent out by the MAC. If <a href="#">SPIx0C[TrackMacLockEn]</a> ==1, the controller unlocks the SPI bus for the MAC. In other words, access by the CPU is allowed again.                                                                                                                                         |
| 15:8  | <b>MacLockCmd1.</b> IF ( <a href="#">SPIx00[SpiAccessMacRomEn]</a> ==0    <a href="#">SPIx00[SpiHostAccessRomEn]</a> ==0) THEN Read-only. ELSE Read-write. ENDIF. Reset: 20h. Same as MacLockCmd0.                                                                                                                                                                                                                                                                                                                                              |
| 7:0   | <b>MacLockCmd0.</b> IF ( <a href="#">SPIx00[SpiAccessMacRomEn]</a> ==0    <a href="#">SPIx00[SpiHostAccessRomEn]</a> ==0) THEN Read-only. ELSE Read-write. ENDIF. Reset: 6h. This is used to compare against the opcode sent out by the MAC. If <a href="#">SPIx0C[TrackMacLockEn]</a> ==1, the controller locks the SPI bus for the MAC. In other words, the MAC has the exclusive access to the ROM and access by the CPU is delayed until this is unlocked. This allows the MAC to do a certain sequence of operations without interruption. |

### SPIx14 SPI\_CmdValue1

| Bits  | Description                                                                                                                                                                                                                                                                                                                          |
|-------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31:24 | <b>RDSR.</b> IF ( <a href="#">SPIx00[SpiAccessMacRomEn]</a> ==0    <a href="#">SPIx00[SpiHostAccessRomEn]</a> ==0) THEN Read-only. ELSE Read-write. ENDIF. Reset: 5h. This is used to compare against the opcode sent out by the MAC. This is a predefined value to decode for the RDSR (read status register) command from the MAC. |
| 23:16 | <b>RDID.</b> IF ( <a href="#">SPIx00[SpiAccessMacRomEn]</a> ==0    <a href="#">SPIx00[SpiHostAccessRomEn]</a> ==0) THEN Read-only. ELSE Read-write. ENDIF. Reset: 9Fh. This is used to compare against the opcode sent out by the MAC. This is a predefined value to decode for the RDID (read ID) command from the MAC.             |
| 15:8  | <b>WRDI.</b> IF ( <a href="#">SPIx00[SpiAccessMacRomEn]</a> ==0    <a href="#">SPIx00[SpiHostAccessRomEn]</a> ==0) THEN Read-only. ELSE Read-write. ENDIF. Reset: 4h. This is used to compare against the opcode sent out by the MAC. This is a predefined value to decode for the WRDI (write disable) command from the MAC.        |
| 7:0   | <b>WREN.</b> IF ( <a href="#">SPIx00[SpiAccessMacRomEn]</a> ==0    <a href="#">SPIx00[SpiHostAccessRomEn]</a> ==0) THEN Read-only. ELSE Read-write. ENDIF. Reset: 6h. This is used to compare against the opcode sent out by the MAC. This is a predefined value to decode for the WREN (write enable) command from the MAC.         |

**SPIx18 SPI\_CmdValue2**

| Bits  | Description                                                                                                                                                                                                                                                                                                                    |
|-------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31:24 | <b>BYTEWR.</b> IF ( <a href="#">SPIx00</a> [SpiAccessMacRomEn]==0    <a href="#">SPIx00</a> [SpiHostAccessRomEn]==0) THEN Read-only. ELSE Read-write. ENDIF. Reset: 2h. This is used to compare against the opcode sent out by the MAC. This is a predefined value to decode for the BYTEWR (byte write) command from the MAC. |
| 23:16 | Reserved.                                                                                                                                                                                                                                                                                                                      |

**SPIx1E SpiExtRegIndx**

| Bits | Description                                                                                                                                             |
|------|---------------------------------------------------------------------------------------------------------------------------------------------------------|
| 7:0  | <b>SPI_ExtReg_Indx.</b> Read-write. Reset: 0. Specifies the offset of the extended SPI register to be read/written from <b>SPIx1F [SpiExtRegData]</b> . |

**SPIx1F SpiExtRegData**

| Bits | Description                                                                                                         |
|------|---------------------------------------------------------------------------------------------------------------------|
| 7:0  | <b>SPI_ExtReg_Data.</b> Read-write. Reset: 00h. Specifies the read data or write data of the extended SPI register. |

**SPIx1F\_x00 DDR\_CMD**

| Bits | Description                                                                                                                                                                  |
|------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 7:0  | <b>DDR_CMD.</b> Read-write. Reset: 3Bh. Specifies the command value to be used when host is doing a Dual Output Read. This is programmable to accommodate different opcodes. |

**SPIx1F\_x01 QDR\_CMD**

| Bits | Description                                                                                                                                                                  |
|------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 7:0  | <b>QDR_CMD.</b> Read-write. Reset: 6Bh. Specifies the command value to be used when host is doing a Quad Output Read. This is programmable to accommodate different opcodes. |

**SPIx1F\_x02 DPR\_CMD**

| Bits | Description                                                                                                                                                                               |
|------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 7:0  | <b>DPR_CMD.</b> Read-write. Reset: BBh. Specifies the command value to be used when host is doing a Dual IO High Performance Read. This is programmable to accommodate different opcodes. |

**SPIx1F\_x03 QPR\_CMD**

| Bits | Description                                                                                                                                                                               |
|------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 7:0  | <b>QPR_CMD.</b> Read-write. Reset: EBh. Specifies the command value to be used when host is doing a Quad IO High Performance Read. This is programmable to accommodate different opcodes. |

**SPIx1F\_x04 ModeByte**

| Bits | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
|------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 7:0  | <b>ModeByte.</b> Read-write. Reset:0. Bits [7:4] of this field control the length of the next Dual/Quad IO High Performance instruction through the inclusion or exclusion of the first byte instruction code. Bits [3:0] of this field are don't care bits (“x”). If ModeByte == Axh, then the device remains in Dual IO High Performance Read Mode and the next address can be entered (after CS# is raised high and then asserted low) without requiring the instruction opcode. Whenever DPR_CMD or QPR_CMD is used, ModeByte is also sent out onto the SPI stream. |

**SPIx1F\_x05 TxByteCount**

| Bits | Description                                                                                    |
|------|------------------------------------------------------------------------------------------------|
| 7:0  | <b>TxByteCount.</b> Read-write. Reset: 0. Specifies the number of bytes to be sent to SPI ROM. |

**SPIx1F\_x06 RxByteCount**

| Bits | Description                                                                                              |
|------|----------------------------------------------------------------------------------------------------------|
| 7:0  | <b>RxByteCount.</b> Read-write. Reset: 0. Specifies the number of bytes to be received from the SPI ROM. |

**SPIx1F\_x07 SPIDataFifoPtr**

| Bits | Description                                                                                        |
|------|----------------------------------------------------------------------------------------------------|
| 7:0  | <b>SpiDataFiFoPtr.</b> Read-only. Reset: 0. Specifies the current pointer of read/write Data FIFO. |

**SPIx20 SPI100 Enable**

| Bits | Description                                                                                                                                                                                                           |
|------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0    | <b>UseSpi100.</b> Read-write. Reset: 0. BIOS: see 2.15.4.2. 0=Use the old SPI engine; Do not support 100 MHz speed. 1=Use the new SPI100 engine; Support 100 MHz speed. The actual read speed also depends on SPIx22. |

**SPIx22 SPI100 Speed Config**

| Bits  | Description                                                                                                                                                                               |                   |             |                   |
|-------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------------|-------------|-------------------|
| 15:12 | <b>NormSpeedNew[3:0].</b> Read-write. Reset: 0011b . Configures the SPI bus normal speed in new SPI100 engine. If the command is not using TpmSpeed and FastSpeed, it will use NormSpeed. |                   |             |                   |
|       | <u>Bits</u>                                                                                                                                                                               | <u>Definition</u> | <u>Bits</u> | <u>Definition</u> |

#### SPIx40 DDRCmdCode

| Bits | Description                                                                                          |
|------|------------------------------------------------------------------------------------------------------|
| 7:0  | <b>DDR_CMD</b> . Read-write. Reset: 3Bh. This is the shadow register of <a href="#">SPIx1F_x00</a> . |

#### SPIx41 QDRCmdCode

| Bits | Description                                                                                          |
|------|------------------------------------------------------------------------------------------------------|
| 7:0  | <b>QDR_CMD</b> . Read-write. Reset: 6Bh. This is the shadow register of <a href="#">SPIx1F_x01</a> . |

#### SPIx42 DPRCmdCode

| Bits | Description                                                                                          |
|------|------------------------------------------------------------------------------------------------------|
| 7:0  | <b>DPR_CMD</b> . Read-write. Reset: BBh. This is the shadow register of <a href="#">SPIx1F_x02</a> . |

**SPIx43 QPRCmdCode**

| Bits | Description                                                                                          |
|------|------------------------------------------------------------------------------------------------------|
| 7:0  | <b>QPR_CMD</b> . Read-write. Reset: EBh. This is the shadow register of <a href="#">SPIx1F_x03</a> . |

**SPIx44 ModeByte**

| Bits | Description                                                                                         |
|------|-----------------------------------------------------------------------------------------------------|
| 7:0  | <b>ModeByte</b> . Read-write. Reset: 0. This is the shadow register of <a href="#">SPIx1F_x04</a> . |

**SPIx45 CmdCode**

| Bits | Description                                                                                                 |
|------|-------------------------------------------------------------------------------------------------------------|
| 7:0  | <b>SpiOpCode</b> . Read-write. Reset: 0. This is the shadow register of <a href="#">SPIx00[SpiOpCode]</a> . |

**SPIx47 CmdTrigger**

| Bits | Description                                                                                                                            |
|------|----------------------------------------------------------------------------------------------------------------------------------------|
| 7    | <b>Excute</b> . Write-1-only; cleared-by-hardware. Reset: 0. This bit is the shadow register of <a href="#">SPIx00[ExcuteOpCode]</a> . |
| 6:0  | Reserved.                                                                                                                              |

**SPIx48 TxByteCount**

| Bits | Description                                                                                            |
|------|--------------------------------------------------------------------------------------------------------|
| 7:0  | <b>TxByteCount</b> . Read-write. Reset: 0. This is the shadow register of <a href="#">SPIx1F_x05</a> . |

**SPIx4B RxByteCount**

| Bits | Description                                                                                            |
|------|--------------------------------------------------------------------------------------------------------|
| 7:0  | <b>RxByteCount</b> . Read-write. Reset: 0. This is the shadow register of <a href="#">SPIx1F_x06</a> . |

**SPIx4C SpiStatus**

| Bits  | Description                                                                                      |
|-------|--------------------------------------------------------------------------------------------------|
| 31    | <b>SpiBusy</b> . Read-only; updated-by-hardware. Reset: 0. 1=SPI bus is busy. 0=SPI bus is idle. |
| 30:23 | Reserved.                                                                                        |
| 22:16 | <b>FiFoRdPtr</b> . Read-only; updated-by-hardware. Reset: 0. The current Data FIFO read pointer. |
| 15    | Reserved.                                                                                        |

|      |                                                                                                                                                     |
|------|-----------------------------------------------------------------------------------------------------------------------------------------------------|
| 14:8 | <b>FiFoWrPtr.</b> Read-only; updated-by-hardware. Reset: 0. The current Data FIFO write pointer.                                                    |
| 7:0  | <b>DoneByteCount.</b> Read-only; updated-by-hardware. Reset: 0. Indicates how many bytes has been received or sent in the previous SPI transaction. |

**SPIx[C6:80] FIFO[70:0]**

---

| Bits | Description                                                                                                           |
|------|-----------------------------------------------------------------------------------------------------------------------|
| 7:0  | <b>FiFo.</b> Read-write. Reset: 0. Contains the Data FiFo byte which is used in command mode to send or receive data. |

### 3.26.10 High Precision Event Timer (HPET) Registers

HPET registers are accessed through two methods:

- Memory access through HPET base address defined by [PMx50 \[HPETEn\]](#):
  1. Program the HPET base address through [PMx50\[HpetBaseAddress\]](#).
  2. Enable HPET address decoding through [PMx50\[HpetDecodeEn\]](#).
- Memory mapped or IO mapped access through the AcpiMmio region. The HPET registers range from [PMx24\[AcpiMmioAddr\]+C00h](#) to [PMx24\[AcpiMmioAddr\]+CFFh](#). See [PMx24 \[AcpiMmioEn\]](#).

#### HPETx000 ID

| Bits  | Description                                                                                                  |
|-------|--------------------------------------------------------------------------------------------------------------|
| 31:16 | <b>VendorID</b> . Read-only. Reset: 1022h.                                                                   |
| 15    | <b>LegacyCap</b> . Read-only. Reset: 1. Legacy replacement interrupt is supported.                           |
| 14    | Reserved.                                                                                                    |
| 13    | <b>CounterSizeCap</b> . Read-only. Reset: 0. Main counter is 32-bits wide and cannot operate in 64-bit mode. |
| 12:8  | <b>NumTmrCap</b> . Read-only. Reset: 2h. Three timers are supported.                                         |
| 7:0   | <b>RevID</b> . Read-only. Reset: 10h. Revision ID.                                                           |

#### HPETx004 ClkPeriod

| Bits | Description                                                                                                                                                                                                                                                                                        |
|------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31:0 | <b>CounterClkPeriod</b> . Read-only; updated-by-hardware. Reset: 429B17Eh. Specifies the clock period of each HPET timer tick. HPET main counter runs at 14.31818 MHz. The unit is femtosecond ( $10^{-15}$ seconds). The value of this register can be modified through <a href="#">MISCx74</a> . |

#### HPETx010 Config

| Bits | Description                                                                                                                                                                 |
|------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31:2 | Reserved.                                                                                                                                                                   |
| 1    | <b>LegacyEn</b> . Read-write. Reset: 0. 1=Timer0 interrupt goes to IRQ0 of PIC controller, INT2 of IOAPIC; Timer1 interrupt goes to IRQ8 of PIC controller, INT8 of IOAPIC. |
| 0    | <b>TmrEn</b> . Read-write. Reset: 0. 0=Pause main counter and disable all timer interrupts. 1=Allow main counter to run and allow timer interrupts if enabled.              |

#### HPETx020 Interrupt Status

| Bits | Description                                                                                                                                                                                                                                                                                               |
|------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31:3 | Reserved.                                                                                                                                                                                                                                                                                                 |
| 2    | <b>Tmr2IntrSts</b> . IF (HPETx140[TmrIntTyp]==1) THEN Read; set-by-hardware; write-1-to-clear. ELSE Read-write. ENDIF. Reset: 0. 0=Timer2 interrupt is not active. 1=Timer2 interrupt is active. If Timer2 is set to edge-triggered mode, software should ignore this bit and always write 0 to this bit. |

|   |                                                                                                                                                                                                                                                                                                          |

This register is updated by hardware when (HPETx1[4:0:Step2]0[TmrTyp] == 1) && the current value in this register matches with the value in HPETx0F0 [Main Counter]. |

### 3.26.11 Miscellaneous (MISC) Registers

MISC register space is accessed through the AcpiMmio region, which can be memory mapped or IO mapped. The MISC registers range from **PMx24**[AcpiMmioAddr]+E00h to **PMx24**[AcpiMmioAddr]+EFFh. See **PMx24** [AcpiMmioEn].

#### MISCx00 GPPClkCntl

BIOS: See 2.15.9.1.

| 11:8        | <p><b>GPP_CLK2_ClockRequestMapping.</b> Read-write. Reset: Fh. GPP2 PCIE clock pins (GPP_CLK2P/GPP_CLK2N) output control by CLK_REQ# pin. GPP_CLK2P/GPP_CLK2N pins are powered off when FCH is strapped to use an external clock, and powered on when FCH is strapped to operate in integrated clock mode. When FCH is in integrated clock mode, GPP2 PCIE clock can be powered off according to the CLK_REQ mapping table below, and the selected CLK_REQ# input can power off the GPP2 PCIE clock output pins if it is asserted.</p> <p>GPP2_CLKREQ_Mapping:</p> <table> <tr> <th><u>Bits</u></th><th><u>Definition</u></th></tr> <tr> <td>0000b</td><td>Off</td></tr> <tr> <td>0001b</td><td>CLK_REQ0#</td></tr> <tr> <td>0010b</td><td>CLK_REQ1#</td></tr> <tr> <td>0011b</td><td>CLK_REQ2#</td></tr> <tr> <td>0100b</td><td>CLK_REQ3#</td></tr> <tr> <td>1001b-0101b</td><td>Reserved; Off</td></tr> <tr> <td>1010b</td><td>CLK_REQGfx#</td></tr> <tr> <td>1110b-1011b</td><td>Reserved; Off</td></tr> <tr> <td>1111b</td><td>On</td></tr> </table> | <u>Bits</u> | <u>Definition</u> | 0000b | Off | 0001b | CLK_REQ0# | 0010b | CLK_REQ1# | 0011b | CLK_REQ2# | 0100b | CLK_REQ3# | 1001b-0101b | Reserved; Off | 1010b | CLK_REQGfx# | 1110b-1011b | Reserved; Off | 1111b | On |

| 7:4         | <p><b>GPP_CLK1_ClockRequestMapping.</b> Read-write. Reset: Fh. GPP1 PCIE clock pins (GPP_CLK1P/GPP_CLK1N) output control by CLK_REQ# pin. GPP_CLK1P/GPP_CLK1N pins are powered off when FCH is strapped to use an external clock and powered on when FCH is strapped to operate in integrated clock mode. When FCH is in integrated clock mode, GPP1 PCIE clock can be powered off according to the CLK_REQ mapping table below, and the selected CLK_REQ# input can power off GPP1 PCIE clock output pins if it is asserted.</p> <p>GPP1_CLKREQ_Mapping:</p> <table> <tr> <th><u>Bits</u></th><th><u>Definition</u></th></tr> <tr> <td>0000b</td><td>Off</td></tr> <tr> <td>0001b</td><td>CLK_REQ0#</td></tr> <tr> <td>0010b</td><td>CLK_REQ1#</td></tr> <tr> <td>0011b</td><td>CLK_REQ2#</td></tr> <tr> <td>0100b</td><td>CLK_REQ3#</td></tr> <tr> <td>1001b-0101b</td><td>Reserved; Off</td></tr> <tr> <td>1010b</td><td>CLK_REQGfx#</td></tr> <tr> <td>1110b-1011b</td><td>Reserved; Off</td></tr> <tr> <td>1111b</td><td>On</td></tr> </table>     | <u>Bits</u> | <u>Definition</u> | 0000b | Off | 0001b | CLK_REQ0# | 0010b | CLK_REQ1# | 0011b | CLK_REQ2# | 0100b | CLK_REQ3# | 1001b-0101b | Reserved; Off | 1010b | CLK_REQGfx# | 1110b-1011b | Reserved; Off | 1111b | On |

| 3:0         | <p><b>GPP_CLK0_ClockRequestMapping.</b> Read-write. Reset: Fh. GPP0 PCIE clock pins (GPP_CLK0P/GPP_CLK0N) output control by CLK_REQ# pin. GPP_CLK0P/GPP_CLK0N pins are powered off when FCH is strapped to use an external clock and powered on when FCH is strapped to operate in integrated clock mode. When FCH is in integrated clock mode, GPP0 PCIE clock can be powered off according to the CLK_REQ mapping table below, and the selected CLK_REQ# input can power off the GPP0 PCIE clock output pins if it is asserted.</p> <p>GPP0_CLKREQ_Mapping:</p> <table> <tr> <th><u>Bits</u></th><th><u>Definition</u></th></tr> <tr> <td>0000b</td><td>Off</td></tr> <tr> <td>0001b</td><td>CLK_REQ0#</td></tr> <tr> <td>0010b</td><td>CLK_REQ1#</td></tr> <tr> <td>0011b</td><td>CLK_REQ2#</td></tr> <tr> <td>0100b</td><td>CLK_REQ3#</td></tr> <tr> <td>1001b-0101b</td><td>Reserved; Off</td></tr> <tr> <td>1010b</td><td>CLK_REQGfx#</td></tr> <tr> <td>1110b-1011b</td><td>Reserved; Off</td></tr> <tr> <td>1111b</td><td>On</td></tr> </table> | <u>Bits</u> | <u>Definition</u> | 0000b | Off | 0001b | CLK_REQ0# | 0010b | CLK_REQ1# | 0011b | CLK_REQ2# | 0100b | CLK_REQ3# | 1001b-0101b | Reserved; Off | 1010b | CLK_REQGfx# | 1110b-1011b | Reserved; Off | 1111b | On |

| 26          | <b>EXT_CLK_ClockSourceOverride.</b> Read-write. Reset: 0. EXT_CLK clock source override control. EXT_CLK clock source is controlled by strap (LPCCLK1). If Strap (LPCCLK1) == 1, clock source is from CG_PLL. If Strap (LPCCLK1) == 0, clock source is from external clock chip through GPP_CLK3_P/N pins. This override bit allows to invert the strap that controls EXT_CLK clock source. 0=Use the strap value (LPCCLK1) to determine whether EXT_CLK clock source from either CG_PLL or external clock chip. 1=Invert the strap that controls EXT_CLK clock source.                                                                                                                                                                                           |             |                   |     |                                                           |     |                                               |     |                                                  |     |                                                  |

| Bits | Description |
|------|-------------|
|------|-------------|

### 3.26.12 GPIO Pin control registers

The GPIO pins are controlled by a combination of device enables and by their specific [GPIOx\[E4:00\]](#) and [IOMUXx\[E4:00\]](#) register pair.

#### 3.26.12.1 GPIO Registers

GPIO register space is accessed through the AcpiMmio region, which can be memory mapped or IO mapped. The registers range from [PMx24\[AcpiMmioAddr\]+100h](#) to [PMx24\[AcpiMmioAddr\]+1FFh](#). See [PMx24\[AcpiMmioEn\]](#).

#### GPIOx[E4:00] GPIO

BIOS: See [2.15.6](#).

| Bits | Description                                                                                                                                                                                                                                         |
|------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 7    | <b>GpioIn.</b> Read-only; updated-by-hardware. Reset: 0. Current pin state.                                                                                                                                                                         |
| 6    | <b>GpioOut.</b> Read-write; S3-check-exclude. Reset: 0. Output state when GpioOutEnB is enabled.                                                                                                                                                    |
| 5    | <b>GpioOutEnB.</b> Read-write. Reset: 1. 0=Output enable. 1=Output disable.                                                                                                                                                                         |
| 4    | <b>PullDown.</b> Read-write. Reset: 0. 0=Pull down disabled. 1=Pull down enabled.                                                                                                                                                                   |
| 3    | <b>PullUpB.</b> Read-write. Reset: 0. 1=Pull up disabled. 0=Pull up enabled.                                                                                                                                                                        |
| 2    | <b>Sticky.</b> Read-write. Reset: 0. 1=Bits[6:3] are sticky and can be reloaded to the default value on PCI reset. 0=Bits [6:3] can be reloaded to the default value on RsmRst and SYS_RST#. This will allow every GPIO to be sticky or non-sticky. |
| 1    | <b>OwnedByHost.</b> Read-write. Reset: 0. This bit can only be written by host (BIOS). If this bit is set, only host can write to bits[6:2] and bit 0 can no longer be written by IMC. This bit is always sticky.                                   |
| 0    | <b>OwnedByEc.</b> Read-write. Reset: 0. This bit can only be written by IMC. If this bit is set, only IMC can write to bits[6:2] and bit 1 can no longer be written by host. This bit is always sticky.                                             |

#### 3.26.12.2 IOMUX Registers

IOMUX register space is accessed through the AcpiMmio region, which can be memory mapped or IO mapped. The registers range from [PMx24\[AcpiMmioAddr\]+D00h](#) to [PMx24\[AcpiMmioAddr\]+DFFh](#). See [PMx24\[AcpiMmioEn\]](#).

**IOMUXx[E4:00] IoMux**

### 3.26.13 Power Management (PM) Registers

PM register space is accessed through two methods:

- Indirect IO access through [IOCD6 \[PM\\_Index\]](#) and [IOCD7 \[PM\\_Data\]](#). Software first programs the offset into the index register [IOCD6](#) and then reads from/writes to the data register [IOCD7](#).
- Direct memory mapped or IO mapped access through the AcpiMmio region. The PM registers range from [PMx24\[AcpiMmioAddr\]+300h](#) to [PMx24\[AcpiMmioAddr\]+3FFh](#). See [PMx24](#) for details on how to set up the AcpiMmio region.

|------|------------------------------------------------------------------------------------------------|
| 31:8 | <b>BiosRamMemAddr</b> . Read-write. Reset: FED100h. Specifies the BIOS RAM base address[31:8]. |
| 7:2  | Reserved.                                                                                      |
| 1    | <b>BiosRamMemPmEnable</b> . Read-write. Reset: 0. 1=Enable BIOS RAM auto-deep-sleep mode.      |
| 0    | <b>BiosRamMemEnable</b> . Read-write. Reset: 0. 1=Enable BIOS RAM access.                      |

**PMx24 AcpiMmioEn**

The AcpiMmio region mapping is disabled at initial power up. Software needs to program it using the indirect IO access through the index register [IOCD6 \[PM\\_Index\]](#) and the data register [IOCD7 \[PM\\_Data\]](#):

1. Select the AcpiMmio region to be memory mapped or IO mapped through [PMx24\[AcpiMmioSel\]](#)
2. Program the base address through [PMx24\[AcpiMmioAddr\]](#).
3. Enable the direct mapping through [PMx24\[AcpiMmioDecodeEn\]](#).

### PMx58 VRT\_T1

| Bits | Description                                                                                                                                                                                                                                                                                                                                                                                                                                    |
|------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 7:0  | <b>VRT_T1.</b> Read-write. Cold reset: 1. This field specifies the time of VRT_Enable being high for RTC battery monitor circuit in milliseconds. To conserve power, the RTC battery is sampled periodically for checking its state of health. VRT_T1 and <a href="#">PMx59[VRT_T2]</a> make up the interval of the checking. When VRT_Enable is high, the battery is being sampled. When VRT_Enable is low, the battery is not being sampled. |

### PMx59 VRT\_T2

| Bits | Description                                                                                                                                                                                                            |
|------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 7:0  | <b>VRT_T2.</b> Read-write. Cold reset: FFh. This field specifies the time of VRT_Enable being low for the RTC battery monitor circuit in 4 ms increments. See <a href="#">PMx58 [VRT_T1]</a> for detailed description. |

### PMx5B RTC Shadow

| Bits | Description                                                                                                                                                           |
|------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 3:0  | <b>PwrFailShadow.</b> Read-write. Cold reset: 0. BIOS: 0100b. Writing to these four bits sets the value of bits [7:4] above. Software should always program bit[2]=1. |

**PMx5C LLBCntrl**

| Bits | Description                                                                                                                                                                                                                                                                                                                                                                                         |

**PMx5F\_x10 RTCEXT WeekTimerControl**

The 16-bit Week Timer is a battery-powered down counter timer that supports 1ms, 1 second, and 1minute resolution and auto reloads when the timer reaches 0. The WEEK\_ALRM interrupt is asserted when the timer reaches 0 and stays asserted until the timer is disabled.

| Bits        | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                      |             |                   |             |                   |     |          |     |      |     |          |     |          |

| 15   | <b>MaskPmeMsgEn.</b> Read-write. Cold reset: 0. 1=If (PmeMsgEn == 1), PmeAck messages coming from PCIe device are ignored and ACPI S state logic solely uses the timeout mechanism to sequence through the S3 state. This bit is used as an option to guard against multiple PmeAck messages coming from CNB and internal FCH PCIe bridges so that FCH S state logic does not sequence into S3 state prematurely. |

| 111b | If CPU is in C state and the controller has already exhausted the link list, it can simply stop the asynchronous packets until CPU resumes back to C0 state. In this case, the controller will resume back to its standard mode.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |      |            |      |                      |      |                                         |      |                                         |      |                                         |      |                                           |      |          |      |          |      |                                                                                                                                                                                                                                  |

### 3.26.14 Power Management Block 2 (PM2) Registers

PM2 register space is accessed through two methods:

- Indirect IO access through index/data address pair at IOCD0 [PM2\_Index] and IOCD1 [PM2\_Data]. Software first programs the offset into the index register IOCD0 [PM2\_Index] and then reads/writes to/from the data register IOCD1 [PM2\_Data].
- Direct memory mapped or IO mapped access through the AcpiMmio region. The PM2 registers range from PMx24[AcpiMmioAddr]+400h to PMx24[AcpiMmioAddr]+4FFh. See PMx24 [AcpiMmioEn].

#### PM2x01 Fan0Control

When [AutoMode] == 1, the active duty cycle is controlled by the hardware automatically.

- If ActualTemperature < LowTemp{PM2x07, PM2x06}, DutyCycle = 0;
- If LowTemp{PM2x07, PM2x06} <= ActualTemperature < MedTemp{PM2x09, PM2x08}, DutyCycle = PM2x03 [LowDuty0].
- If MedTemp{PM2x09, PM2x08} <= ActualTemperature < HighTemp{PM2x0B, PM2x0A},
  - If [LinearMode] == 0, DutyCycle = PM2x04 [MedDuty0].
  - If [LinearMode] == 1, DutyCycle = ((ActualTemperature - LowTemp{PM2x07, PM2x06}) \* (PM2x05[Multiplier] + 1) >> PM2x05[DutySel]) + PM2x03 [LowDuty0].
- If ActualTemperature >= HighTemp{PM2x0B, PM2x0A}, DutyCycle = 100%.

In Automode, hysteresis limit defined by PM2x0C [LinearRange0] is applied to keep the fan from oscillating erratically.

### PM2x05 Multiplier0

When (PM2x01[AutoMode] == 1) && (PM2x00[TwoRampAlgorithm] == 1), Fan0 is in TwoRamp mode. The slope value of ramp1 and ramp0 is: Slope[7:0] = {PM2x05[DutySel], PM2x05[Multiplier]}. Slope[7:2] are the integer bits and Slope[1:0] are the fractional bits of the ramp slope.

BIOS has to calculate Slope[7:0] using the following equation:

$$\text{Slope} = (16'hFF00 - \{\text{LowDuty0}[7:0], 8'b0\}) / (\text{HighTemp0}[15:0] - \text{Hysteresis0}[15:0] - \text{MedTemp0}[15:0])$$

For example, if our setting is:

$$\text{LowDuty0}[7:0] = 25\% = 40h$$

$$\text{HighTemp0}[15:0] = 90^{\circ}\text{C} = 5A00h$$

$$\text{MedTemp0}[15:0] = 40^{\circ}\text{C} = 2800h$$

$$\text{Hysteresis0}[15:0] = 10^{\circ}\text{C} = 0A00h$$

Then:

$$\text{Slope} = (FF00h - 4000h) / (5A00h - 0A00h - 2800h) = 48896 / 10240 = 4.775$$

Convert the number 4.775 into our 8-bit format: 00010011b (13h). BIOS should program the Multiplier0 register as 13h in this example.

| Bits | Description                                                                                                                                                                                                                                                                                                                                                                        |
|------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 7:6  | <b>DutySel.</b> Read-write. Reset: 0. When Fan0 is programmed in AutoMode with linear function being selected, this field selects part of duty to be fed into fan as described in PM2x01 [Fan0Control] register description. When Fan0 is programmed in TwoRamp mode, this field specifies the upper 2 bits in Slope[7:0]. See the above register description for detail.          |
| 5:0  | <b>Multiplier.</b> Read-write. Reset: 0. When Fan0 is programmed in AutoMode with linear function being selected, this field specifies the factor to calculate duty number as described in PM2x01 [Fan0Control] register description. When Fan0 is programmed in TwoRamp mode, this field specifies the lower 6 bits in Slope[7:0]. See the above register description for detail. |

### PM2x06 LowTemp0Lo

| Bits | Description                                                                                          |
|------|------------------------------------------------------------------------------------------------------|
| 7:0  | <b>LowTemp0[7:0].</b> Read-write. Reset: 0. Specifies the lower 8 bits of low temperature threshold. |

### PM2x07 LowTemp0Hi

| Bits | Description                                                                                            |
|------|--------------------------------------------------------------------------------------------------------|
| 7:0  | <b>LowTemp0[15:8].</b> Read-write. Reset: 0. Specifies the higher 8 bits of low temperature threshold. |

### PM2x08 MedTemp0Lo

| Bits | Description                                                                                             |
|------|---------------------------------------------------------------------------------------------------------|
| 7:0  | <b>MedTemp0[7:0].</b> Read-write. Reset: 0. Specifies the lower 8 bits of medium temperature threshold. |

**PM2x09 MedTemp0Hi**

| Bits | Description                                                                                                |
|------|------------------------------------------------------------------------------------------------------------|
| 7:0  | <b>MedTemp0[15:8]</b> . Read-write. Reset: 0. Specifies the higher 8 bits of medium temperature threshold. |

**PM2x0A HighTemp0Lo**

| Bits | Description                                                                                             |
|------|---------------------------------------------------------------------------------------------------------|
| 7:0  | <b>HighTemp0[7:0]</b> . Read-write. Reset: 0. Specifies the lower 8 bits of high temperature threshold. |

**PM2x0B HighTemp0Hi**

| Bits | Description                                                                                               |
|------|-----------------------------------------------------------------------------------------------------------|
| 7:0  | <b>HighTemp0[15:8]</b> . Read-write. Reset: 0. Specifies the higher 8 bits of high temperature threshold. |

**PM2x0C LinearRange0**

| Bits | Description                                                                                                                                                 |
|------|-------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 7:0  | <b>LinearRange</b> . Read-write. Reset: 0. Specifies a variable range that Fan0 can tolerate. Fan0 is not affected if temperature varies within this range. |

**PM2x0D LinearHoldCount0**

| Bits | Description                                                                                                            |
|------|------------------------------------------------------------------------------------------------------------------------|
| 7:0  | <b>LinearHoldCount</b> . Read-write. Reset: 0. Specifies the fan cycles to be waited before duty cycle can be changed. |

**PM2x0E Fan0Hysteresis**

| Bits | Description                                                                                                                                                                                                                  |
|------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 15:8 | <b>HysteresisHi</b> . Read-write. Reset: 0. Specifies the hysteresis value (in temperature) of the Two Ramp Fan Control Algorithm. The unit is °C. See <a href="#">PM2x05 [Multiplier0]</a> on how to program this register. |
| 7:0  | <b>HysteresisLo</b> . Read-write. Reset: 0. Reserved. This byte should always be programmed as 0.                                                                                                                            |

**PM2x50 Med2Temp0Lo**

| Bits | Description                                                                                                                                                                                                        |
|------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 7:0  | <b>Med2Temp0[7:0]</b> . Read-write. Reset: 0. IF ( <a href="#">PM2x00[TwoRampAlgorithmEn]</a> ==1) THEN It specifies the lower byte of the temperature value of the turning point on the ramp. ELSE Unused. ENDIF. |

**PM2x51 Med2Temp0Hi**

| Bits | Description                                                                                                                                                                                        |
|------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 7:0  | <b>Med2Temp0[15:8]</b> . Read-write. Reset: 0. IF (PM2x00[TwoRampAlgorithmEn]==1) THEN It specifies the higher byte of the temperature value of the turning point on the ramp. ELSE Unused. ENDIF. |

**PM2x52 Med2Duty0**

| Bits | Description                                                                                                                                                                 |
|------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 7:0  | <b>Med2Duty0[7:0]</b> . Read-write. Reset: 0. IF (PM2x00[TwoRampAlgorithmEn]==1) THEN It specifies the fan duty value of the turning point on the ramp. ELSE Unused. ENDIF. |

**PM2x53 Multiplier2\_0**

BIOS has to calculate Multiplier2\_0[7:0] using the following equation:

$$\text{Multiplier2\_0} = (\{\text{Med2Duty0}[7:0], 8'b0\} - \{\text{LowDuty0}[7:0], 8'b0\}) / (\text{Med2Temp0}[15:0] - \text{MedTemp0}[15:0])$$

For example, if our setting is:

PM2x52[Med2Duty0[7:0]]=50%=80h

PM2x03[LowDuty0[7:0]]=25%=40h

Med2Temp0[15:0]={PM2x51, PM2x50}=70°C=4600h

MedTemp0[15:0]={PM2x09, PM2x08}=40°C=2800h

Then:

$$\text{Multiplier2\_0}[7:0] = (8000h - 4000h) / (4600h - 2800h) = 16384 / 7680 = 2.133$$

Convert the number 4.775 into our 8bit format: 00001000b (08h). BIOS should program Multiplier2\_0 register as 08h in this example.

| Bits  | Description                                                                                                                                                                                                                                                                                                                                                                  |     |            |       |                                |       |                                   |

**3.26.15 Standard ACPI Registers**

These are the standard registers defined by the ACPI specification. In order to access these ACPI registers, [PMx74\[DecEnAcpi\]](#) must be programmed to 1. ACPI registers are accessed through two methods:

- IO mapped access through base addresses defined by [PMx60](#) through [PMx6E](#).
- Memory mapped or IO mapped access through the AcpiMmio region. The ACPI registers range from [PMx24\[AcpiMmioAddr\]+800h](#) to [PMx24\[AcpiMmioAddr\]+8FFh](#). See [PMx24 \[AcpiMmioEn\]](#).

### 3.26.15.1 AcpiPmEvtBlk

The IO mapped base address of this register block is defined by [PMx60](#). Its offset in the AcpiMmio region is 800h.

| 7:0  | <b>PLvl3</b> . RAZ; read-only. Reset: 0. Reads to this register return all zeros and generate an “enter C3” sequence to APU. |

**3.26.15.6 AcpiGpe0Blk**

The IO mapped base address of this register block is defined by [PMx68](#). Its offset in the AcpiMmio region is 814h.

**AcpiGpe0Blkx00 EventStatus**

| Bits | Description                                                                                                                                                                                                                                                                                                                                                                                                            |
|------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31:0 | <b>EventStatus.</b> Read; write-1-to-clear. Reset: X. Each bit represents an ACPI event status. For each bit, 1=The selected event input equals to the corresponding value in <a href="#">SMIx08 [SciTrig]</a> . Configuration for the events are located at <a href="#">SMIx08 [SciTrig]</a> through <a href="#">SMIx78 [SciMap14]</a> . The status bits are also mirrored in <a href="#">SMIx00 [Event_Status]</a> . |

**AcpiGpe0Blkx04 EventEnable**

| Bits | Description                                                                                                                                                                                     |
|------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31:0 | <b>EventEnable.</b> Read-write. Reset: 0. Each bit controls whether ACPI should generate wakeup and SCI interrupt. The enable bits are also mirrored in <a href="#">SMIx04 [Event_Enable]</a> . |

**3.26.15.7 SmiCmdBlk**

The IO mapped base address of this register block is defined by [PMx6A](#). Its offset in the AcpiMmio region is 81Ch.

**SmiCmdBlkx00 SmiCmdPort**

| Bits | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
|------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 7:0  | <b>SmiCmdPort.</b> Read-write. Reset: 0. When SMI command port is enabled, a write to this port generates SMI, NMI or IRQ3 depending on the setting of <a href="#">SMIxB0[23:22]</a> . A read from this port returns the previously written value but does not generate SMI. The SMI command port has to be located at an even address (ie, 0, 2, 4, 6, 8, A, C, or E). SmiCmdStatus is always located one byte immediately after the SmiCmdPort. The implementation actually contains four (4) bytes of address space. If SMI command port is assigned to byte 0, then byte 1 is SmiCmdStatus. Byte 2 and 3 can be used as scratch. If SmiCmdPort is assigned to byte 2, then bytes 0 and 1 are not available. |

**SmiCmdBlkx01 SmiCmdStatus**

| Bits | Description                                                     |
|------|-----------------------------------------------------------------|
| 7:0  | <b>SmiCmdStatus.</b> Read-write. Reset: 0. Used by BIOS and OS. |

### 3.26.16 SMI Registers

SMI register space is accessed through the AcpiMmio region, which can be memory mapped or IO mapped. The SMI registers range from [PMx24\[AcpiMmioAddr\]+200h](#) to [PMx24\[AcpiMmioAddr\]+2FFh](#). See [PMx24\[AcpiMmioEn\]](#).

#### SMIx00 Event\_Status

| Bits | Description                                                                                                                                                                                                                                                                                     |
|------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31:0 | <b>EventStatus.</b> Read; write-1-to-clear. Reset: X. This is a mirror register of the standard ACPI register <a href="#">AcpiGpe0Blkx00 [EventStatus]</a> . Each event status bit is set when the selected event input equals to the corresponding value in <a href="#">SMIx08 [SciTrig]</a> . |

#### SMIx04 Event\_Enable

| Bits | Description                                                                                                                                                                                                                  |
|------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31:0 | <b>EventEnable.</b> Read-write. Reset: 0. This is the mirror register of the standard ACPI register <a href="#">AcpiGpe0Blkx04 [EventEnable]</a> . Each bit controls whether ACPI should generate wake up and SCI interrupt. |

#### SMIx08 SciTrig

Each bit in this register controls the way to set each corresponding bit in [SMIx00 \[Event\\_Status\]](#).

| Bits | Description                                                                                                               |
|------|---------------------------------------------------------------------------------------------------------------------------|
| 31   | <b>SciTrig31.</b> Read-write. Reset: 1. The bit controls the way to set Event_Status bit 31. 0=Active low. 1=Active high. |
| 30   | <b>SciTrig30.</b> Read-write. Reset: 1. The bit controls the way to set Event_Status bit 30. 0=Active low. 1=Active high. |
| 29   | <b>SciTrig29.</b> Read-write. Reset: 1. The bit controls the way to set Event_Status bit 29. 0=Active low. 1=Active high. |
| 28   | <b>SciTrig28.</b> Read-write. Reset: 1. The bit controls the way to set Event_Status bit 28. 0=Active low. 1=Active high. |
| 27   | <b>SciTrig27.</b> Read-write. Reset: 1. The bit controls the way to set Event_Status bit 27. 0=Active low. 1=Active high. |
| 26   | <b>SciTrig26.</b> Read-write. Reset: 1. The bit controls the way to set Event_Status bit 26. 0=Active low. 1=Active high. |
| 25   | <b>SciTrig25.</b> Read-write. Reset: 1. The bit controls the way to set Event_Status bit 25. 0=Active low. 1=Active high. |
| 24   | <b>SciTrig24.</b> Read-write. Reset: 1. The bit controls the way to set Event_Status bit 24. 0=Active low. 1=Active high. |
| 23   | <b>SciTrig23.</b> Read-write. Reset: 1. The bit controls the way to set Event_Status bit 23. 0=Active low. 1=Active high. |
| 22   | <b>SciTrig22.</b> Read-write. Reset: 1. The bit controls the way to set Event_Status bit 22. 0=Active low. 1=Active high. |

|    |                                                                                                                             |
|----|-----------------------------------------------------------------------------------------------------------------------------|
| 21 | <b>SciTrig21.</b> Read-write. Reset: 1. The bit controls the way to set Event_Status bit 21. 0=Active low. 1=Active high.   |
| 20 | <b>SciTrig20.</b> Read-write. Reset: 1. The bit controls the way to set Event_Status bit 20. 0=Active low. 1=Active high.   |
| 19 | <b>SciTrig19.</b> Read-write. Reset: 1. The bit controls the way to set Event_Status bit 19. 0=Active low. 1=Active high.   |
| 18 | <b>SciTrig18.</b> Read-write. Reset: 1. The bit controls the way to set Event_Status bit 18. 0=Active low. 1=Active high.   |
| 17 | <b>SciTrig17.</b> Read-write. Reset: 1. The bit controls the way to set Event_Status bit 17. 0=Active low. 1=Active high.   |
| 16 | <b>SciTrig16.</b> Read-write. Reset: 1. The bit controls the way to set Event_Status bit 16. 0=Active low. 1=Active high.   |
| 15 | <b>SciTrig15.</b> Read-write. Reset: 1. The bit controls the way to set Event_Status bit 15. 0=Active low. 1=Active high.   |
| 14 | <b>SciTrig14.</b> Read-write. Reset: 1. The bit controls the way to set Event_Status bit 14. 0=Active low. 1=Active high.   |
| 13 | <b>SciTrig13.</b> Read-write. Reset: 1. The bit controls the way to set Event_Status bit 13. 0=Active low. 1=Active high.   |
| 12 | <b>SciTrig12.</b> Read-write. Reset: 1. The bit controls the way to set Event_Status bit 12. 0=Active low. 1=Active high.   |
| 11 | <b>SciTrig11.</b> Read-write. Reset: 1. The bit controls the way to set Event_Status bit 11. 0=Falling edge. 1=Active high. |
| 10 | <b>SciTrig10.</b> Read-write. Reset: 1. The bit controls the way to set Event_Status bit 10. 0=Active low. 1=Active high.   |
| 9  | <b>SciTrig9.</b> Read-write. Reset: 1. The bit controls the way to set Event_Status bit 9. 0=Active low. 1=Active high.     |
| 8  | <b>SciTrig8.</b> Read-write. Reset: 1. The bit controls the way to set Event_Status bit 8. 0=Active low. 1=Active high.     |
| 7  | <b>SciTrig7.</b> Read-write. Reset: 1. The bit controls the way to set Event_Status bit 7. 0=Active low. 1=Active high.     |
| 6  | <b>SciTrig6.</b> Read-write. Reset: 1. The bit controls the way to set Event_Status bit 6. 0=Active low. 1=Active high.     |
| 5  | <b>SciTrig5.</b> Read-write. Reset: 1. The bit controls the way to set Event_Status bit 5. 0=Active low. 1=Active high.     |
| 4  | <b>SciTrig4.</b> Read-write. Reset: 1. The bit controls the way to set Event_Status bit 4. 0=Active low. 1=Active high.     |
| 3  | <b>SciTrig3.</b> Read-write. Reset: 1. The bit controls the way to set Event_Status bit 3. 0=Active low. 1=Active high.     |
| 2  | <b>SciTrig2.</b> Read-write. Reset: 1. The bit controls the way to set Event_Status bit 2. 0=Active low. 1=Active high.     |
| 1  | <b>SciTrig1.</b> Read-write. Reset: 1. The bit controls the way to set Event_Status bit 1. 0=Active low. 1=Active high.     |
| 0  | <b>SciTrig0.</b> Read-write. Reset: 1. The bit controls the way to set Event_Status bit 0. 0=Active low. 1=Active high.     |

**SMIx0C SciLevl**

Reset: 0000\_0000h. This register specifies the trigger mode for each of the corresponding bit in [SMIx00 \[Event\\_Status\]](#).

| Bits | Description                                                    |
|------|----------------------------------------------------------------|
| 31   | <b>SciLevl31.</b> Read-write. 0=Edge trigger. 1=Level trigger. |
| 30   | <b>SciLevl30.</b> Read-write. 0=Edge trigger. 1=Level trigger. |
| 29   | <b>SciLevl29.</b> Read-write. 0=Edge trigger. 1=Level trigger. |
| 28   | <b>SciLevl28.</b> Read-write. 0=Edge trigger. 1=Level trigger. |
| 27   | <b>SciLevl27.</b> Read-write. 0=Edge trigger. 1=Level trigger. |

| 5    | <b>SciLevl5.</b> Read-write. 0=Edge trigger. 1=Level trigger.  |
| 4    | <b>SciLevl4.</b> Read-write. 0=Edge trigger. 1=Level trigger.  |
| 3    | <b>SciLevl3.</b> Read-write. 0=Edge trigger. 1=Level trigger.  |
| 2    | <b>SciLevl2.</b> Read-write. 0=Edge trigger. 1=Level trigger.  |
| 1    | <b>SciLevl1.</b> Read-write. 0=Edge trigger. 1=Level trigger.  |
| 0    | <b>SciLevl0.</b> Read-write. 0=Edge trigger. 1=Level trigger.  |

**SMIx10 SmiSciStatus**

| Bits | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
|------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31:0 | <b>SmiSciStatus.</b> Read; write-1-to-clear. Reset: 0. Each bit indicates the corresponding SmiSci status. The input of each bit is controlled by the corresponding <a href="#">SMIx08 [SciTrig]</a> bit. Note: this function can be considered as a superset of <a href="#">SMIx00 [Event_Status]</a> . When one of the bits is set and its <a href="#">SMIx14 [SmiSciEn]</a> is also set, it triggers a SMI to call the BIOS. After the BIOS has serviced the SMM and cleared its status, the internal logic automatically sets the corresponding <a href="#">SMIx00 [Event_Status]</a> bit and thereby triggering a SCI. |

**SMIx14 SmiSciEn**

| Bits | Description                                                                                                                                                                                                                                                                                                                                                                                       |
|------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31:0 | <b>SmiSciEn.</b> Read-write; S3-check-exclude. Reset: 0. Each bit controls if SMI message is generated when the corresponding <a href="#">SMIx10 [SmiSciStatus]</a> bit is set to 1. For each bit, 0=Not to send SMI message when the corresponding <a href="#">SMIx10 [SmiSciStatus]</a> bit is set. 1=Send SMI message when the corresponding <a href="#">SMIx10 [SmiSciStatus]</a> bit is set. |

**SMIx18 SwSciEn**

| Bits | Description                                                                                                                                                                                                                                                                                                                                                                                               |
|------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31:0 | <b>SwSciEn.</b> Read-write. Reset: 0. This register is used as a software mechanism to trigger SCI. For each bit, 1=Software can write to <a href="#">SMIx1C [SwSciData]</a> and set the corresponding <a href="#">SMIx00 [Event_Status]</a> bit. Note: the setting of this bit needs to match with <a href="#">SMIx08 [SciTrig]</a> and <a href="#">SMIx0C [SciLevl]</a> in order to set the status bit. |

**SMIx1C SwSciData**

| Bits | Description                                                                                                                                                                             |
|------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31:0 | <b>SwSciData.</b> Read-write. Reset: 0. This is the software data path to set the corresponding <a href="#">SMIx00 [Event_Status]</a> bit when <a href="#">SMIx18 [SwSciEn]</a> is set. |

**SMIx20 SciSleepDisable**

| Bits | Description                                                                                                                                                                                                                                                                                                           |
|------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31:0 | <b>SciSleepDisable.</b> Read-write. Reset: 0. This register is used to ignore EVENT pins that are powered in the main power domain instead of auxiliary power domain. For each bit, 1=The corresponding <a href="#">SMIx00 [Event_Status]</a> bit is masked off whenever the system goes to S3 or higher sleep state. |

**SMI<sub>x</sub>30 CapturedData**

| Bits | Description                                                                                                                                                                        |
|------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31:0 | <b>CapturedData</b> . Read-only. Reset: X. This is the buffer to capture write data for the last transaction that caused an SMI. Note: this buffer has no meaning for a read trap. |

**SMI<sub>x</sub>34 CapturedValid**

### SMIx94 SmiPointer

This register is meant as a faster mechanism to locate the SMI source. BIOS can examine this register to find out the SMI source instead of reading [SMIx80 \[SmiStatus0\]](#) through [SMIx90 \[SmiStatus4\]](#) individually.

| Bits | Description                                                                                                                                                             |

### SMIx96 SmiTimer

There are two SMI timers: the short timer runs at 1 us unit time and the long timer runs at 1 ms unit time. This register is actually made up of two sets of registers depending on the setting of [SMIx98\[SmiTimerSel\]](#). If [SMIx98\[SmiTimerSel\]==0](#), then [SMIx96](#) is for the short timer. If [SMIx98\[SmiTimerSel\]==1](#), then [SMIx96](#) is for the long timer. The default setting selects this register as “SmiShortTimer”; software needs to set the “SmiTimerSel=1” to select this register as “SmiLongTimer”.

| Bits | Description                                                                                                                                              |
|------|----------------------------------------------------------------------------------------------------------------------------------------------------------|
| 15   | <b>TimerEn</b> . Read-write. Reset: 0. 1=Enable the SMI short Timer or long timer, which is selected by <a href="#">SMIx98[SmiTimerSel]</a> . 0=Disable. |
| 14:0 | <b>SmiTimerCount</b> . Read-write. Reset: 0. Actual timer duration = TimerTime + 1 unit.                                                                 |

### SMIx98 SmiTrig0

Bit [23:0] defines the trigger mode for 24 GEVENTS in [SMIx80\[23:0\]](#). Note these are different from [SMIx08 \[SciTrig\]](#).

| Bits | Description                                                                                                                                                                                 |
|------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31   | <b>SmiEnB</b> . Read-write. Reset: 1. 0=Enable SMI function. 1=Disable.                                                                                                                     |

### 3.26.17 Watchdog Timer (WDT) Registers

Watchdog timer registers are accessed through two methods:

- Memory access through watchdog timer base address defined by [PMx48 \[WatchdogTimerEn\]](#):
  1. Program the watchdog timer base address through [PMx48\[WatchdogBase\]](#).
  2. Enable watchdog timer address decoding through [PMx48\[WatchdogDecodeEn\]](#).
- Memory mapped or IO mapped access through the AcpiMmio region. The WDT registers start from [PMx24\[AcpiMmioAddr\]+B00h](#). See [PMx24 \[AcpiMmioEn\]](#).

#### WDTx00 WatchdogControl

| Bits | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
|------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31:8 | Reserved.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| 7    | <b>WatchdogTrigger</b> . RAZ; write-1-only. Reset: 0. Writing 1 to this bit triggers the watchdog to start a new count interval, counting down from the value that was last written to <a href="#">WDTx04</a> . Setting this bit has no effect if the watchdog is disabled or stopped.                                                                                                                                                                                                                                                            |
| 6:4  | Reserved.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| 3    | <b>WatchdogDisable</b> . Read-only. Reset: 1. This bit reflects the state of the watchdog timer hardware. 0=Enable. 1=Disable. This bit reflects the state of <a href="#">PMx48[WatchdogFuncDisable]</a> .                                                                                                                                                                                                                                                                                                                                        |
| 2    | <b>WatchdogAction</b> . Read-write. Reset: 0. This bit determines the action to be taken when the watchdog timer expires. 0=System reset. 1=System power off. The bit is only valid when the watchdog is enabled.                                                                                                                                                                                                                                                                                                                                 |
| 1    | <b>WatchdogFired</b> . Read; write-1-to-clear. Cold reset: 0. 1=The watchdog timer has expired and caused the current restart. The bit is cleared by a power cycle or by the operating system and it must remain cleared for any restart that is not caused by the watchdog timer firing. The bit is only valid when the watchdog is enabled.                                                                                                                                                                                                     |
| 0    | <b>WatchdogRunStopB</b> . Read-write. Reset: 0. 1=Watchdog is in the running state. 0=Watchdog is in the stopped state. This bit is used to control or indicate whether the watchdog is in the running or stopped states. If the watchdog is in the stopped state and a 1 is written to this bit, the watchdog moves to the running state, but a count interval is not started until a 1 is written to bit [7]. If the watchdog is in the running state, writing 1 to this bit has no effect. The bit is only valid when the watchdog is enabled. |

#### WDTx04 WatchdogCount

| Bits  | Description                                                                                                                                                                                                                                                                                                                |
|-------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31:16 | Reserved.                                                                                                                                                                                                                                                                                                                  |
| 15:0  | <b>WatchdogCount</b> . Read-write. Reset: X. Writing this register specifies the countdown time for the counter. Reading this register returns the current counter value. The units are defined in the Units field in the Watchdog Resource Table (WDRT). The maximum value is defined in the Max Count field in the WDRT. |

### 3.26.18 Wake Alarm Device (AcDcTimer) Registers

The AC/DC timer registers are used to control the wake alarm device. They are accessed through the AcpiMmio region, which can be memory mapped or IO mapped. The AC DC timer registers range from [PMx24\[AcpiMmioAddr\]+1D00h](#) to [PMx24\[AcpiMmioAddr\]+1DFFh](#). See [PMx24 \[AcpiMmioEn\]](#).

**AcDcTimerx00 AcTimerValue**

| 0   | <b>Busy.</b> Read-only; updated-by-hardware. Reset: 0h. Right after <a href="#">AcDcTimerx00 [AcTimerValue]</a> or <a href="#">AcDcTimerx10 [DcTimerValue]</a> is programmed, the hardware sets this bit to 1. The hardware will clear this bit once the programming is done and the corresponding timer is started properly. Before the software writes to <a href="#">AcDcTimerx00 [AcTimerValue]</a> or <a href="#">AcDcTimerx10 [DcTimerValue]</a> , it has to read this bit and make sure it is 0. Otherwise, the hardware will just ignore the programming action from software. For the registers other than <a href="#">AcDcTimerx00 [AcTimerValue]</a> or <a href="#">AcDcTimerx10 [DcTimerValue]</a> , there is no such limitation. |

## 4 Register List

The following is a list of all storage elements, context, and registers provided in this document. Page numbers, register mnemonics, and register names are provided.

|     |                                                     |     |                                                                         |
